(54) Title: FENESTRATION SEALED FRAME, INSULATING GLAZING PANELS

(57) Abstract: A fenestration sealed frame insulating glazing panel has an integral planar frame formed by four rigid plastic profiles interconnected end-to-end to define corners, the profiles having a low heat conductivity. Two glazing sheets are arranged in spaced parallel relationship attached on opposite sides of the frame in rigid manner by thermosetting adhesive to form an integral structure having an insulating cavity enclosed by the frame. The front face of each frame profile presented towards the cavity is covered by a low permeability sealant. The sealed frame glazing panel can include a third glazing sheet positioned in parallel between the first two glazing sheets and likewise interconnected at its perimeter to the frame to divide the insulating cavity into two parallel coextensive sub-cavities. The profiles of the frame can be made from structural plastic foam material, glass fiber, oriented thermoplastic, or various other materials of low thermal conductivity. The glazing panel can be incorporated as a fixed window or as an operating window or door in an external building wall.

5 BACKGROUND OF THE INVENTION

Field of the Invention

This invention relates generally to glazing-and-frame construction and more particularly to fenestration sealed frame, insulating glazing panels.

Description of the Prior Art

A conventional window consists of an insulating glass unit supported within a separate frame. Traditionally, the frame was made from wood or metal profiles but increasingly plastic profiles are being substituted made from such materials as polyvinyl chloride (PVC) or pultruded fibreglass.

20

25

A traditional insulating glass unit generally consists of two or more glass sheets that are typically separated by a hollow aluminum spacer bar that is filled with desiccant bead material. With a conventional dual-seal unit, thermoplastic polyisobutylene material is applied to the spacer sides and the outward facing channel between the glazing sheets and the spacer is filled with structural thermosetting sealant.

Because of the high thermal conductivity of the

30 aluminum spacer, various efforts have been made in recent years
to manufacture the hollow spacer from rigid low conductive
plastic material. US Patent 4,564,540 issued to Davies
describes the substitution of a rigid hollow fibreglass

10

15

20

PCT/CA00/01180

pultrusion for the aluminum spacer. Although a substantial development effort was carried out, this product has not yet been successfully commercialized and the technical problems include: moisture wicking at the corners; glass stress breakage, and poor argon gas retention.

One solution to the problem of glass stress breakage is to manufacture the spacer from flexible material. US Patent 4,831,799 issued to Glover et al describes a flexible rubber foam spacer that is desiccant filled with pre-applied pressure sensitive adhesive on the spacer sides. This flexible foam spacer has been commercialized under the name of Super Spacer®. In addition to featuring a low conductive spacer, another innovative feature of a Super Spacer® edge seal is that the traditional roles of the two perimeter seals are reversed. The inner PSA seal is the structural seal while the outer seal is the moisture/gas barrier seal that is typically produced using hot melt butyl sealant.

In the past ten years, other warm-edge technologies have been developed where the traditional aluminum spacer has been replaced by a spacer made from a more insulating material and these other warm-edge technologies include: PPG's Intercept® and AFG's Comfort Seal® product. In total, these thermally improved warm-edge technologies have now gained about 25 an 80 per cent share of the North American market.

In addition to reducing perimeter heat loss, these new warm edge products can also improve the efficiency and the speed of manufacturing the insulating glass units. These 30 system improvements include: manufacturing the edge seal as a metal re-enforced butyl strip (Tremco's Swiggle Seal®); roll forming the metal spacer and incorporating butyl desiccant

4

matrix and an outer butyl sealant (PPG's Intercept ®); and manufacturing the spacer from EPDM foam with pre-applied butyl sealant and desiccant matrix (AFG's Comfort Seal®). Although these improvements allow for the automated production of insulating glass units, residential sash windows still tend to be manufactured using largely manual assembly methods and typically, window frame fabrication is more labor intensive than sealed unit production.

One way of improving window assembly productivity is 10 to fully integrate frame and sealed unit assembly. In the presentation notes for the talk entitled Extreme Performance Warm-Edge Technology and Integrated IG/Window Production Systems given at InterGlass Metal '97, Glover describes a PVC sealed frame window system developed by Meeth Fenester in 15 Germany. With this system, there is one continuous IG/window production line and using an automated four point welder, a PVC window frame is assembled around a double glazed unit. As noted in the paper, some of the concerns with the Meeth system include: problem of broken glass replacement; 20 recycling/disposal of PVC window frames, and the technical risks of no drainage holes.

For window energy efficiency, most of the recent

25 focus has been on improving the thermal performance of
insulating glass units. Increasingly, it is being realized
that substantial additional improvements will only be feasible
through the development of new window frame types and
technology. In a technical paper entitled Second Generation

30 Super Windows and Total Solar Home Powered Heating, and
presented at the Window Innovations '95 world conference in
Toronto, Canada, Glover describes a second generation Super
Window consisting of an exterior high performance triple glazed

window and an interior high performance double glazed panel. By using motorized hardware, both the exterior and interior windows overlap the wall opening and this allows for a significant increase in solar gains and overall energy efficiency. However although significant energy efficiency improvements are achieved, the installation of the conventional casement window is very complex and this is primarily due to the extended width of the conventional window frame.

5

PCT/CA00/01180

10 SUMMARY OF THE INVENTION

20

25

30

WO 01/25581

The present invention provides a fenestration sealed frame insulating glazing panel having an integral generally planar frame that is formed by a number of rigid plastic profiles having interconnected ends that define corners of said frame, said plastic profiles being fabricated in a material that has a low heat conductivity compared to aluminum and a coefficient of expansion that is similar to that of glass; two glazing sheets arranged in spaced parallel relationship and attached to opposite sides of said frame to define therewith a sealed insulating cavity; each framing profile in section having a portion that is overlapped by said sheet, said overlapped portion of each framing profile defining on opposite sides thereof an elongate seat to receive a marginal edge region of a corresponding one of said glazing sheets; each said framing profile having a front face that is located between said elongate seats and is directed into said cavity; said glazing sheets being adhered to said seats by a structural sealant material that exhibits thermosetting properties; a low permeability sealant covering the front face of each of said frame profiles and extending towards the structural sealant on opposite sides of each framing profile to provide a continuous

15

20

б

PCT/CA00/01180

seal between said glazing sheets around the periphery of said cavity.

The low permeability sealant that is exposed to the interior of the cavity can incorporate desiccant material.

Preferably there is a decorative strip provided around the perimeter of each glazing sheet to cover or mask the structural sealant.

The rigid plastic profiles can be provided in many different forms, such as glass fiber filled thermoplastic extrusions, glass fiber pultrusions, glass fibre thermoplastic extrusions reinforced with thermoplastic pultruded strips, oriented thermoplastic extrusions, and structural thermoplastic foam extrusions. Whatever material is used in these rigid plastic profiles, it should have a heat conductivity that is low compared to aluminum. Preferably the heat conductivity would be less than 1/100 that of aluminum. For example whereas the thermal conductivity of aluminum is 160 W/m°C, the thermal conductivity of fibreglass is 0.3 W/m°C, and that of expanded polystyrene foam is 0.03 W/m°C.

A vapor barrier sheet film material can be applied to the front face of each framing profile, and the low permeability sealants may be hot melt butyl or polyisobutylene.

The structural sealant is preferably made from
thermosetting silicone material, and an alternative preferred
material option is for the structural sealant and the low
permeability sealant to be a single material that has both

thermoplastic and thermosetting properties, for example in modified silicone material or a reactive hot melt butyl material.

7

PCT/CA00/01180

A third glazing sheet can be positioned between the two outer glazing sheets and this third glazing sheet which is the same shape but smaller in size than the outer glazing sheets and typically, this third glazing sheet is directly adhered to a stepped frame profile.

10

15

5

The fenestration sealed frame insulating glazing panel of the invention may be utilized as a door or a window panel in an exterior building wall. Where the panel is mounted to be moveable, suitable operating devices are attached to the plastic frame for connection to an operating mechanism in the window or door frame in the building wall. When used as a window, one preferred option is for the glazing panel to be mounted in an overlapping relationship to an opening in the wall of the exterior side thereof.

20

25

30

In an alternative configuration the glazing panel in accordance with the invention may be utilized to provide ribbon windows in a building wall. In this arrangement, each panel is positioned so that it spans between top and bottom supports, the side edges of adjacent panels being in abutment but otherwise being unsupported.

The fenestration sealed frame glazing insulating panel of the present invention is self supporting and may be designed to carry structural loads, in this case the glazing sheets being made of laminated glass. In such a stressed skin structural panel, the glazing sheets are preferably spaced apart by at least 70 mm, and the panel can incorporate a

PCT/CA00/01180

passage through which air can enter and leave the interior cavity, such passage incorporating desiccant to remove moisture from air that enters the cavity between the sheets.

8

5 BRIEF DESCRIPTION OF DRAWINGS

WO 01/25581

The following is a description by way of example of certain embodiments of the present invention, reference being made to the accompanying drawings, in which:

DETAILED DESCRIPTION OF DRAWINGS

10

20

Referring to the drawings, Figure 1 shows an elevation view of a sealed frame, triple-glazed panel 21 that functions as an operable exterior door. The glazing door panel 21 consists of three glazing sheets 23, 24 (not shown) and 25 (not shown) that are adhered to a narrow width perimeter 15 frame 26. The panel 21 is edge supported using hinges 27 that are mechanically attached to the narrow width perimeter frame. The handle and locking mechanism 28 for the operable door are incorporated in a rectangular panel 29 that forms part of the outer perimeter frame 26. The glazing door panels are typically made from heat strengthened or tempered glass sheets although rigid clear plastic sheets can be substituted.

Although an entrance door is illustrated in Figure 1, sealed frame construction can also be used for other glass door 25 types including patio and accordion doors. For these different door assemblies, sealed frame construction creates a visually attractive, slim-line aesthetic as well as improved overall energy efficiency. According to the Canadian energy rating system, a conventional double-glazed, wood frame door can have 30 an energy rating of ER minus 30. In contrast, a sealed frame, triple-glazed door incorporating energy efficient features such as low-e coatings and argon gas fill can have an energy rating

11

as low-e coatings and argon gas fill can have an energy rating as high as ER plus 15. The reasons for the dramatic performance improvement are twofold. First, low-e coatings and inert gas improve thermal performance and reduce heat loss. Second with higher performance glazing, there is no drawback if glazing area is increased and with the narrow sealed-frame profile widths, the glazing area can be increased by over 30 per cent and this results in increased solar gains and higher energy efficiency.

10

15

Figure 2. shows a cross-section of a sealed frame. triple-glazed panel 21. The perimeter frame 26 is assembled from rigid plastic, stepped-frame profiles 30 that are joined together and sealed at the corners. Glazing sheets 23 and 24 overlap the perimeter frame 26 and are adhered to the frame using sealant material 33. A third glazing sheet 25 is located between two outer glazing sheets 23 and 24 and this third glazing sheet 25 is similar in shape but smaller in size than the center two glazing sheets 23 and 24.

20

The glazing sheets 23, 24 and 25 are typically made from heat strengthened or tempered glass. For optimum thermal performance, the width of the cavity spaces 41 and 42 between the glazing sheets 23, 24 and 25 is typically about 12.5 mm (% inch). For further improved energy efficiency, a low-e coating 51 can be applied to one or more of the glass cavity surfaces of the glazing panel 21. In addition, the cavity spaces 41 and 42 between the glazing sheets 23, 24 and 25 can incorporate a low conductive gas such as argon or krypton.

30

25

For triple-glazed panels, one major advantage of the stepped frame profile is improved condensation resistance. The bottom edge cold air convection currents 57 within the outer

glazing cavity 41 do not coincide with the bottom edge cold air convection currents 58 within the inner glazing cavity 42 and as a result, bottom edge glazing temperatures can be quite significantly increased.

12

PCT/CA00/01180

5

10

15

20

25

The rigid plastic profiles 30 can be made from various materials using various different production processes. As illustrated in Figure 2, the stepped frame profiles 30 are made from thermoplastic extrusions 31 that are heat welded at the corners. Various thermoplastic materials can be used and one preferred material is glass fibre-filled poly vinyl chloride (PVC). Particularly for larger frame assemblies such as doors, the extrusion can be further reinforced with strips of thermoplastic fiber glass pultrusions 32. One key advantage of this composite assembly is increased strength and rigidity. A second key advantage is that the thermal coefficient of expansion of the composite assembly is similar to the thermal coefficient expansion of glass and as a result, there is minimum stress on the sealant material. The thermoplastic profile extrusion 31 is subdivided into a series of cavities 59 and this provides for additional rigidity and strength as well as improved thermal performance.

An optional barrier film 34 is laminated to the stepped profiles 30 and this film 34 extends from the two top side edges 35 and 36 and across the two front faces 37 and 38. The barrier film 34 is also laminated to a tongue shaped portion 39 located between the glazing sheets 24 and 25.

Low permeable sealant 40 is applied continuously to the barrier film 34 creating a continuous barrier of sealant material between the glazing sheets 23 and 24. This low permeable sealant 40 must be non-outgassing and preferred

PCT/CA00/01180

materials include hot melt butyl and polyisobutylene sealants. To remove moisture vapor from the glazing cavity spaces 41 and 42, the low permeable sealant incorporates desiccant fill material 61 with 3A molecular sieve desiccant being the preferred material.

The preferred material for the barrier film 34 is a saran-coated, metallized plastic film that is thermally bonded to the rigid plastic profile. The purpose of the barrier film 34 is to provide a secondary barrier for moisture protection and inert gas retention. However, the use of the barrier film is optional and assuming that the low permeable sealant 40 can be consistently and accurately applied, there is no need for this secondary barrier protection.

15

10

5

WO 01/25581

The glazing sheets 23 and 24 are adhered to the framing profile 30 with structural thermosetting sealant 60 that is applied to the bottom portions 43 and 44 of the extended projection 45. Various thermosetting sealant materials can be used and because of proven durability, one preferred material is one or two part silicone sealant. The center glazing sheet 25 is held in position by means of a Z-shaped clip 46 that is held in position by the sealant material 33.

25

30

20

To hide the perimeter edge-seal, decorative plastic film strips 47 and 48 are applied to the perimeter edges 49 and 50 of the glazing sheets 23 and 24. Typically the decorative strips are made from dual tone material with the inner surface being colored black while the outer surface is typically white or another contrasting color.

An additional strip 52 is applied to the perimeter

PCT/CA00/01180

edge 53 of the center glazing sheet 25 and the outward surface is typically a dark color such as black. The top edge of the decorative strip 52 is lined up with the top edges of the outer decorative strips 47 and 48. When viewed at the oblique angle, the dark colored surfaces visually merge together creating the visual illusion of a solid profile and as a result, the stepped portion of the frame is not visually noticeable.

The decorative strips 47 and 48 can be made from

various materials and one preferred material option is

polyethylene terephthalate (PET) plastic film that is double

coated with fluoroelastomer paint. The strips 47 and 48 are

adhered to the outer perimeter edges 49 and 50 of the glazing

sheets 23 and 24 with acrylic pressure sensitive adhesive 56.

A second preferred material option is to produce the strips

from fluoro-elastomer coatings that are directly applied to the

glass. For color matching, the exposed outer surfaces of the

plastic profile 30 can also be coated with the same fluoro
elastomer coatings used for the strips.

20

WO 01/25581

Figure 3 shows a sealed frame, triple-glazed door panel 21 that is similar in construction to the door panel illustrated in Figure 2 but the assembly incorporates a series of alternative materials and sub components.

25

30

For example, the center glazing sheet 25 is a rigid transparent plastic sheet 62. In comparison with conventional glass, the advantage of using a rigid plastic center glazing is that it provides for improved security protection and hurricane resistance. The plastic sheet can be made from various materials including polycarbonate and acrylic sheet.

The rigid plastic profiles 30 are made from a

WO 01/25581

thermoplastic polyurethane glass fibre pultrusion 63 that is marketed by Dow Plastics under the trade name of Fulcrum. The glass fibre content of the thermoplastic pulruded material can be as high as 80 per cent and as a result, the material is very stiff and rigid with the coefficient of thermal expansion being very similar to that of glass. Hollow pultruded profiles 63 are connected together with corner keys and are thermally bonded at the corners to ensure a long term, durable seal. For improved thermal performance, the hollow profiles 63 are filled with low density insulating foam 72.

PCT/CA00/01180

An optional barrier film 34 can be laminated and adhered to the hollow profile using pressure sensitive adhesives. Alternatively, the barrier film 34 can be applied during the pultrusion process and this has the advantage that the film can be coated with a thin layer of polyurethane material which helps ensure that the film cannot be accidentally damaged or punctured prior to the assembly of the sealed frame panel.

20

25

30

10

15

Instead of using a combination of thermoplastic and structural thermosetting sealant, a single thermoplastic/thermosetting sealant 64 can be used. The key advantage of using a single material is that automated sealant application is greatly simplified. With the stepped triple-glazed profile, the sealant is continuously applied from the bottom side edges 43 and 44, across the front faces 37 and 38 on the tongue portion 39. Various thermosetting/thermoplastic sealant materials can be used including: reactive hot melt butyl, modified silicone and modified polyurethane materials. In all three cases, the sealant is applied as a hot melt thermoplastic material but overtime, the sealant chemically cures as a thermosetting material. The sealant material

PCT/CA00/01180

16

incorporates desiccant fill material and one preferred material is Delchem D-2000 reactive hot melt butyl that is produced by Delchem of Wilmington, Delaware. To protect the sealant from direct UV exposure, silicone sealant beads 71 can be applied in the gaps 65 and 66 between the bottom glass edges and the framing profiles.

The decorative pattern strips 47 and 48 are located on the inner face of the glazing sheets 23 and 24. The

10 decorative strips 47 and 48 are made from ceramic frit material that is bonded to the glass at high temperatures.

Although the perimeter frame is typically assembled from rigid plastic profiles, it can be appreciated by those skilled-in-the-art that the frame can also be manufactured in one piece using injection molding production processes. The main drawback is the high cost of the large molds which means in effect that only a very limited number of standard sizes can be cost effectively manufactured.

20

15

Figure 4 illustrates the main production steps involved in the assembly of the sealed frame, triple-glazed panel illustrated in Figure 3.

25 Figure 4A shows an exploded perspective corner view of two hollow thermoplastic pultruded profiles 75 and 76 that have been miter cut and are then joined together with a tight fitting corner key 77. To provide for a durable and long term hermetic seal, the thermoplastic corner key 77 can be bonded to the thermoplastic frame profiles 75 and 76 and this can be achieved using various production techniques, including electromagnetic welding and magnetic heat sealing.

17

PCT/CA00/01180

Figure 4B shows a perspective view of the corner frame assembly where thermoplastic/thermosetting sealant is continuously applied from the bottom side edges 43 and 44, across the front faces 37 and 38 and the tongue portion 39 of the hollow profiles 75 and 76. Using special robotic heads, the sealant is extruded around the complex profile shape. At the corner, the robotic head moves out and then rotates through 90 degrees. Typically, this turning operation results in excess sealant 78 in the corners, but because the corners are the weak link in edge seal integrity, this excess corner sealant is generally advantageous. On the side faces 79 at the corners, it is difficult to achieve consistent sealant thickness and so a secondary smoothing operation may be required to achieve uniform application.

15

20

25

Figure 4C shows a partially exploded perspective view of the corner frame assembly where a first glazing sheet 25 is matched with the frame assembly 80. The glazing sheet 25 overlaps the tongue portion 39 of the framing profiles 75 and 76. Using robotic automated equipment, the center glass sheet 25 is very accurately located so that the sealant on the front face 35 is not disturbed and seal integrity is maintained. A second glass sheet 23 is also accurately positioned against the side wall 82 with the glass sheet edges 68 being located a uniform distance from the outer profile ledges 70. The glass/frame subassembly is then rotated through 180 degrees and after which a third glass sheet 24 is accurately positioned against the side wall 83 using automated robotic equipment.

After the glazing sheets 23 and 24 have been accurately matched, the thermoplastic/ thermosetting sealant is then fully wet out by applying heat and pressure to the sealant material. As well as wetting out the sealant, the heat and

15

20

25

30

18

PCT/CA00/01180

pressure also increases the structural bond strength and also initiates the curing process. Depending on the profile shape either a conventional roller press can be used or alternatively the thermoplastic sealant can be wet out by means of pressure rollers that automatically move around the perimeter edge of the glazing sheets 23 and 24.

After the triple glazing panel has cooled down, the sealed cavities and are filled with an inert gas, such as argon or krypton. Both the inner and outer fill holes through the 10 hollow profile are plugged and typically, these plugs are made of thermoplastic material that can be thermally welded to the thermoplastic profile. Compared to conventional window frame assembly, a key advantage of sealed frame construction is that for operable windows and doors, it is feasible for the panels to be easily refilled on site and so there is no thermal performance degradation due to long term gas loss.

For fabricating the perimeter rigid frame profiles, various other plastic materials and production processes can be used. As shown in Figure 5A, the profile 84 can be extruded from a glass fibre-filled thermoplastic material. One preferred product material is glass fiber-filled polyvinyl chloride (PVC) plastic with the glass fibre content varying between 10 and 30 per cent and one supplier of this product is Polyone of Cleveland, Ohio who produces this product under the trade name of Fiberlock. As shown in Figure 5B, the profile 85 can be extruded from glass fibre re-enforced, thermoplastic, structural foam materials such as polycarbonate or polyimides. As shown in Figure 5C the profile 86 can also be pultruded made from a thermosett plastic, glass fibre composite. Compared to thermoplastic pultrusions, the main drawback of thermosett pultrusions is the need to achieve reliable hermetic corner

sealing using conventional sealant materials. Finally as illustrated in Figure 5D, the extruded profile 87 can be made from an oriented thermoplastic material such as polyethylene or polypropylene. During the extrusion process, the thermoplastic material is effectively stretched with the highly oriented material having significantly modified properties such that the thermal coefficient of expansion is somewhat similar to that of glass.

19

Compared to aluminum and other metals, the four alternative plastic materials have comparatively low thermal conductivities. For example in the case of fibreglass, the thermal conductivity is 0.3 W/m°C while in comparison the thermal conductivity of aluminum is 160 W/m°C. However compared to fiber glass pultrusions, the thermal conductivity of other plastic materials are much lower and for example, the thermal conductivity of expanded polystyrene foam is 0.03 W/m°C.

Also, the four alternative plastic materials have a coefficient of expansion somewhat similar to glass and this helps ensure that there is minimum differential expansion between the glass sheets and the rigid plastic profiles.

Figures 1 to 5 show the use of sealed frame

25 construction for glass doors where the key advantage is
improved energy efficiency through the use of slim-line narrow
profile frames. In addition to glass doors, sealed frame
construction also offers performance advantages for both fixed
and operable windows.

30

Particularly for overlap casement windows, sealed frame construction offers the advantage that panel width can be

reduced and as a result, the overlap window can have a similar width to the outer rigid foam wall insulation. This greatly helps to simplify installation and allows the insulated wall to be sandwiched between the inner and outer frames. As a result, energy efficiency is increased and solar gains are maximized. For example according to the Canadian energy rating system, a conventional double glazed window can have an ER minus 25 rating. while a high performance double, single overlap window can have an ER plus 25 rating.

20

PCT/CA00/01180

10

15

20

30

Figure 6 shows a vertical cross-section of an overlapping casement window assembly. For increased energy efficiency, a sealed frame glazing casement window 90 is installed on the exterior side of the insulated wood frame building wall 91 and this window completely overlaps the framed wall opening 92. Plaster dry wall sheeting 93 is directly attached to the wood frame members on the top 94 and sides (not shown) of the opening 92. A wood sill 95 is directly attached to the bottom frame member 96. The wood sill 95 incorporates a channel groove 97 and a single glazed interior panel 98 is supported within the groove. A magnetic flexible rubber gasket 99 is adhered to the perimeter edge 100 of the interior panel 98. When the interior panel 98 is in position, an airtight seal is created between the flexible rubber magnetic gasket and 25 the buried metal dry wall angle 101. In the summer months when the interior glazing panel 98 is removed, there are no visible attachment devices. For further improved energy efficiency, a low-e coating 51 is typically incorporated on surface five of the triple panel 21. A low density EPDM rubber foam extrusion 150 can also be attached to the insect screen support rail 118.

Figure 7 shows a bottom cross-section detail of the outer overlap window 127. The casement sash frame 128 is

fabricated from fibreglass filled PVC extrusions. Glazing sheets 23, 24 and 25 are adhered to the extended projection 45 of sash frame 128. The sash frame is supported using specialized integrated overlap window hardware (not shown) that combines the support hinges, multi- point locking devices and window operator into a single integrated component. The hardware can be operated manually or by means of a single electrical motor.

21

PCT/CA00/01180

A flat rigid outer profile 106 is snap fitted to the casement sash frame 128 creating a window hardware chamber 108. The outer rain screen weather stripping 105 is also attached to the bottom end 109 of the rigid profile 106. The top end 111 of the rigid profile is a decorative feature that overlaps and hides the perimeter edge seal 118. The rigid profile can be from made a variety of materials including aluminum and pultruded fiberglass.

The main air barrier seal is a conventional EPDM

20 rubber gasket 112. The outer window frame 110 is made from conventional PVC plastic extrusions that are thermally welded at the corners. The outer PVC frame 110 is directly screw fixed to the wood framing member 114 that forms part of the insulated wall construction 115. The bottom leg 104 of the PVC window frame 110 extends outwards for a minimum of 50mm and is overlapped by the rigid foam insulation 117.

In addition to residential windows and doors, sealedframe construction also offers advantages for commercial 30 building fenestration systems.

Figure 8 shows an elevation view of a ribbon window assembly 120 for a commercial building where the fixed sealed

frame, insulating glazing panels 121 span unsupported between a top 122 and bottom frame member 123.

22

PCT/CA00/01180

Figure 9. shows a horizontal cross-section through two adjacent fixed sealed frame, triple glazing panels 121A and 121B incorporating a stepped frame pultruded fibreglass profile The wider face 125 of the stepped profile is on the 124. exterior side of the building while the narrower face 126 is on the interior side. The inner 24, outer 23 and 25 center glazings are adhered to a stepped frame profile 124 creating a 10 stiff panel assembly that can span unsupported between top and bottom window frame members. Assuming that no special devices like breather tubes are used, and if excessive glass bowing is to be avoided, the maximum overall panel width is about 50 mm. The two glazing panels 121A and 121B are located about 9 mm 15 apart. Polyethylene foam backing rods 127 are located between the glazing panels 121A and 121B. Silicone sealant is used to seal both the inner 128 and the outer 129 joints creating a clean uncluttered band of glass on both the interior and exterior of the building. 20

Even though a 50 mm wide stressed skin glass panel is comparatively stiff, especially when fabricated with rigid fibreglass profiles 124, the maximum span of the panel between the top and bottom supports 122 and 123 is about 1.5 m with the maximum spacing being dependent on such factors as local wind exposure, glass thickness and panel size.

25

Figures 10, 11, and 12 illustrate stressed skin
30 glazing panel construction where the width of the stressed skin
panels are greater than 50 mm. With stressed skin panel
construction, the glass skins are joined and adhered to the
supporting frame so that in combination, the two glass skins

WO 01/25581

and frame structurally act as an integral unit with the two glass skins carrying some of the structural loads so that the combined skin-and-frame assembly has greater load carrying capacity than if its individual members were installed separately.

PCT/CA00/01180

Figure 10 shows an isometric view of an attached sunroom 130 fabricated from stressed skin glass panels. Except for the end panel fascias 132, the combination of the wall and roof panels 131 and 133 create an all-glass exterior 10 and interior look. Each panel incorporates a device 134 that consists of a long thin breather tube filled with desiccant material. As air pressure fluctuates within the sealed unit, air is either sucked in or extracted through the breather tube. The desiccant material within the breather tube dries out the incoming air and ensures that there is no moisture build-up within the stressed skin panels 131 and 134. Eventually, the desiccant material is degraded through moisture build-up and it then has to be replaced on a regular maintenance schedule.

20

25

15

5

Figure 11. shows a cross-section through the attached sunroom 130. The stressed skin wall panels 131 fully support the roof panels 133 and there is no separate structural sub To carry the outward tensile forces from the roof assembly, a tensioned steel rod 151 interconnects the two opposite sides of the sunroom at the wall/roof glazing junction 135.

To provide the required structural stiffness, the glazing sheets, 23 and 24 are spaced apart a minimum of 70 mm 30 apart and preferably at least 100 mm apart with the spacing varying depending on the sunroom geometry, building size, panel size and local climatic conditions such as winter snow and ice

loads.

25

WO 01/25581

In designing the glass stressed skin structure, there is a need for some structural redundancy so that if a single glass sheet randomly shatters or breaks, there is no catastrophic structural failure. Consequently as shown in Figure 12, the stressed skin glazing panels are constructed from an inner and outer laminated glass sheet 136 and 137 where each laminated glass sheet is fabricated from a minimum of two separate tempered or heat strengthened glass sheets 138 and 139 10 that are laminated and adhered together through the use of a PVB inter layer 140.

24

PCT/CA00/01180

For optimum thermal performance of a conventional 15 double glazed insulating glass unit, glazing sheets are spaced about 12 to 15 mm apart because if the glazing sheets are spaced wider apart, there is increased convection flow within the glazing unit and thermal performance is downgraded. One way of dampening convection flow and increasing energy efficiency is through the use of honeycomb convection 20 suppression devices. One preferred convection suppression device 141 is manufactured by Advanced Glazings of Sydney, Nova Scotia. The product is marketed under the name InsolCore.® The product is made from flexible polypropylene plastic film that is heat welded together to form a honeycomb convection suppression device that is suspended between the two glazing sheets.

Figure 12. shows a perspective cross-section view of the joint between two stressed skin glass panels. The panels 30 are fabricated from two laminated glazing sheets 136 and 137 that are spaced apart by hollow, foam-filled, E-shaped, pultruded fibreglass profiles 142. The laminated glazings are

adhered to the profiles using a combination of structural silicone sealant 72 and low permeable, desiccant-filled sealant 40 such as modified silicone sealant or reactive hot melt butyl. Typically, the sealant material is protected from direct UV exposure by decorative strips 47 and 48 (not shown).

25

PCT/CA00/01180

The front face of the profile is coated with low permeable, desiccant filled sealant material. An alternative option is to laminate flat strips of impervious gas/moisture barrier material to the front face of the rigid profile and then continuously overlap these flat strips at the side edges and corners with the same low permeable sealant that is also applied to the side edges.

The two panels 131A and 131B are spaced about 9 mm apart. Both the interior and exterior joints are sealed with silicone sealant 119. Flexible foam strips 143 are attached to both center tongues 144 of the E-shaped profiles 142 creating two separate cavity spaces 145 and 146.

20

10

It should be understood that while for clarity certain features of the invention are described in the context of separate embodiments, these features may also be provided in combination in a single embodiment. Furthermore, various

25 features of the invention which for brevity are described in the context of a single embodiment may also be provided separately or in any suitable sub-combination in other embodiments.

Moreover, although particular embodiments of the invention have been described and illustrated herein, it will be recognized that modifications and variations may readily

26

occur to those skilled in the art, and consequently it is intended that the claims appended hereto be interpreted to cover all such modifications and equivalents.

WO 01/25581 PCT/CA00/01180

CLAIMS:

1. A fenestration sealed frame, insulating glazing panel having an integral generally planar frame that is formed by a number of rigid plastic profiles having interconnected ends that define corners of said frame, said plastic profiles being fabricated in a material that has a low heat conductivity compared to aluminum and a coefficient of expansion that is similar to that of glass;

10

two glazing sheets arranged in spaced parallel relationship and attached to opposite sides of said frame to define therewith a sealed insulating cavity;

each framing profile in section having a portion that is overlapped by said sheets, said overlapped portion of each framing profile defining on opposite sides thereof an elongate seat to receive a marginal edge region of a corresponding one of said glazing sheets

20

each said framing profile having a front face that is located between said elongate seats and is directed into said cavity;

said glazing sheets being adhered to said seats by a structural sealant material that exhibits thermosetting properties;

a low permeability sealant covering the front face of said frame profiles and extending towards the structural sealant on opposite sides of each framing profile to provide a continuous seal between said glazing sheets around the periphery of said cavity.

2. A fenestration sealed frame, insulating glazing panel as claimed in Claim 1 wherein said low permeability sealant incorporates a desiccant material that is exposed to said cavity.

28

5

- 3. A fenestration sealed frame, insulating glazing panel as claimed in Claim 1 where a portion of said frame lies outside the extent of said sheets.
- 10 4. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 3 including a decorative feature applied to the perimeter of at least one said glazing sheet to cover at least part of said structural sealant.
- 15 5. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 4 including a third glazing sheet positioned in parallel relationship between said two glazing sheets, said third glazing sheet having a perimeter that is attached to said frame to divide said sealed insulating cavity into two parallel coextensive sub-cavities.
 - A fenestration sealed frame, insulating glazing panel as claimed in Claim 5 wherein said third glazing sheet is similar in shape to and smaller in size than one of said two glazing sheets, said frame profiles section being of stepped configuration to support said perimeter of the third glazing sheet at a location that is offset towards the interior of said insulating cavities from the perimeter of at least one of said two glazing sheets.

30

25

7. A fenestration sealed frame, insulating glazing panel as claimed in Claim 6 wherein said third glazing is attached to one or more of said two sheets by means of one or more flexible

10

15

20

25

insulating spacers with pre-applied pressure sensitive adhesive on the sides of said spacers.

29

PCT/CA00/01180

- 8. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 7 where said rigid plastic profiles are made from pultruded fibreglass material.
 - 9. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 7 where said rigid plastic profiles are made from structural plastic foam material.
 - 10. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 7 where said rigid plastic profiles are made from oriented thermoplastic material.
 - 11. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 10 where a vapor barrier sheet film material is applied to said front face of said framing profiles.
 - 12. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 11 where said low permeable sealants is selected from hot melt butyl and polyisobutylene.
 - 13. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 11 where said structural sealant is made from thermosetting silicone material.
- 30 14. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 11 where said structural sealant and said low permeable sealant comprise a single material that is a thermoplastic /thermosetting sealant

material.

10

15

25

WO 01/25581

15. A fenestration sealed frame, insulating glazing panel as claimed in Claim 14 where said thermoplastic/thermosetting sealant is made from a modified silicone material.

30

PCT/CA00/01180

- 16. A fenestration sealed frame, insulating glazing panel as claimed in Claim 14 where said thermoplastic/thermosetting sealant is made from a modified polyurethane material.
- 17. A fenestration sealed frame, insulating glazing panel as claimed in Claim 4 where said decorative feature is located on the exterior face of the exterior glazing sheet and where said decorative feature is a thin film strip of fluoroelastomer material that is adhered to said exterior sheet.
- 18. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 17 where one or more operating devices are attached to said plastic profiles and where said devices allow said panel to move between open and closed positions.
- 19. A fenestration sealed frame, insulating glazing panel as claimed in Claim 18 where said panel is a window.
- 20. A fenestration sealed frame, insulating glazing panel as claimed in Claim 18 where said panel is a door.
- 21. A building wall having an exterior side and an interior side, said wall defining therein a window opening defined by a perimeter window frame structure mounted on said wall assembly, in combination with a fenestration sealed frame insulating glazing panel as claimed in any one of Claims 1 to

31

PCT/CA00/01180

20, and where said panel is operable and is mounted on the exterior side of said wall and overlapping said opening throughout the periphery of said opening.

- A fenestration sealed frame, insulating glazing panel of Claim 21 wherein an additional removable glazing panel is located on the interior side of said opening.
- 23. A fenestration sealed frame, insulating glazing panel of Claim 21 wherein said panel overlaps the exterior perimeter frame structure of a building that supports the glazing wall assembly.
- 24. A building wall having an exterior side and an interior side, said wall defining therein a window opening having opposed upper and lower edges on which are respective top and bottom supports; in combination with a fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 17, said panel being fixed in position on said top and bottom supports and spanning the vertical spacing there between, vertical side edges of said panel when installed being unsupported by said building wall.
- 25. A building wall as claimed in Claim 24 wherein a series of adjacent panels span between said bottom and top support and where said adjacent panels are fixed in position.
- A building wall as claimed in Claim 24 where an operable panel is located adjacent to said fixed panel and is supported in part by said fixed panel.
 - 27. A structural panel for use in an exterior building envelope said panel comprising:

PCT/CA00/01180

four straight rigid plastic profiles arranged in a rectangular configuration and interconnected at their ends to form a rectangular peripheral frame;

two rectangular laminated glass sheets each arranged on one side of said frame and having along each edge a marginal band that is seated in overlapping relationship with a respective one of said profiles to form a continuous peripheral engagement between each glass sheet and said frame;

10

15

20

WO 01/25581

wherein said sheets are spaced apart by at least 70mm and are rigidly attached to form an integral structure with said frame by means of thermosetting sealant applied between said profiles and the marginal bans of said sheets, said integral structure comprising a stressed skin panel which is unsupported on at least two sides.

- 28. A structural panel as claimed in Claim 27 wherein said panel incorporates a passage through which air can enter and leave said panel, said passage incorporating a desiccant material to remove moisture in air that enters said panel.
- 29. A structural panel as claimed in Claim 27 where honeycomb transparent insulation is located between the glazing sheets of said panel and where said honeycomb insulation is made from flexible plastic film material.
- 30. A building enclosure fabricated from sealed frame, insulating glazing panels as claimed in any one of Claims 27 to 29 where said panels are self supporting and there is no separate building structural frame.
 - 31. A fenestration sealed frame, insulating glazing panel

PCT/CA00/01180

as claimed in any one of Claims 1 to 7 wherein said rigid plastic profiles are made from glass re-enforced thermoplastic extrusions.

A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 7 wherein said rigid plastic profiles are made from glass fiber-filled thermoplastic extrusions re-enforced with thermoplastic pultruded fibreglass strips

10

WO 01/25581

- A fenestration sealed frame, insulating glazing panel as claimed in Claim 14 wherein said thermoplastic/thermosetting sealant is a reactive hot melt butyl sealant.
- 15 34. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 4 to 7 wherein said decorative feature is located on the exterior face of the exterior glazing sheet and is a rigid profile attached to said frame.
- 20 35. A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 7, where said frame is fabricated in one piece by means of an injection molding production process.
 - A fenestration sealed frame, insulating glazing panel as claimed in any one of Claims 1 to 23 or 31 to 35, where said cavity is filled with an inert gas after said panel has been assembled.

International application No. PCT/CA 00/01180

INTERNATIONAL SEARCH REPORT

Box I	Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)					
This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:						
1.	Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:					
2.	Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:					
3.	Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).					
Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)						
This Inte	ernational Searching Authority found multiple inventions in this international application, as follows:					
	see additional sheet					
1. X	As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.					
2.	As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.					
3.	As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:					
4.	No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:					
Remari	The additional search fees were accompanied by the applicant's protest. No protest accompanied the payment of additional search fees.					

FURTHER INFORMATION CONTINUED FROM PCT/ISAV 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. Claims: 1-26 and 31-36

Insulating glazing panel for windows

2. Claims: 27-30

A structural panel for use in an exterior building envelope
